## Leading Trends Influencing North Dakota's Future Population

North Dakota's population grew only slightly over the past decade. Data from the 2000 Census indicate that the state grew by 0.5 percent between 1990 and 2000 reaching a population base of 642,200. This is the smallest relative growth of all 50 states. Three leading trends are seen to influence the state's future population and comprise the underlying assumptions used to project future county populations within North Dakota: rural depopulation, out-migration of young adults and young families, and an increasing proportion of elderly.

### *Rural Depopulation*

Decades of movement of rural residents to the larger cities have depopulated much of North Dakota. This trend of residential consolidation in North Dakota is very similar to that occurring throughout the Great Plains. In the last decade, population growth occurred largely in the metropolitan and Native American reservation counties of the state. In fact, only six of the state's 53 counties grew between 1990 and 2000 (20 percent in Cass, 15 percent in Burleigh, 8 percent in Sioux, 7 percent in Rolette, 7 percent in Morton, and 2 percent in Ward). The long-term trend of net out-migration is expected to continue. Thus, the majority of counties will continue to lose population. Currently, more than half of the 53 counties in the state have a population base below 5,000 residents. By 2020, nearly half of the counties will have a population base below 4,000 residents.

### *Out-Migration of Young Adults*

In addition to the general trend of rural depopulation, another significant pattern that will have a major consequence on the future of the state's population is the out-migration of young adults and young families. The loss of residents in their twenties and early thirties has increased markedly over the past two decades. This trend has created an age imbalance that is very evident in the population pyramids. The loss of young adults means that there will be fewer parents of childbearing age and therefore fewer children. As a result, the number of children will consistently decline for the majority of counties over the next 20 years.

### *Increasing Proportion of Elderly*

Another noteworthy trend is the increasing proportion of elderly (age 65 and older). In 1980, 12.3 percent of the state's population base was age 65 or older; in 2000, the proportion had increased to 14.7 percent. In addition, 27 of the state's 53 counties had more than 20 percent of their population base older than 64 in 2000. Nationally, the proportion of elderly is only 12.4 percent. In addition, North Dakota has the highest proportion in the nation of elderly 85 years and older. These high proportions of elderly are due, in part, to a modest net in-migration of seniors who are returning to the state to be close to family and friends. Elderly desiring to return to informal care networks, already a growing trend in population redistribution, will contribute to dramatic increases as the baby-boom population ages. If current trends continue, the number of elderly in the state will grow by 58 percent over the next 20 years and represent nearly 23 percent of the state's population. In addition, the number of older seniors (i.e., 85 years of age and older) will grow by nearly two-thirds during that time frame.

These trends pose serious concerns for the state. For example, how will counties remain viable in the face of continued rural depopulation? Population losses, which reduce community size, force residents to face rising costs of, increased travel times to, and decreased availability of goods and services. Can counties and the state ensure adequate healthcare in the face of rural hospital and clinic closings? What will be the impact of further school consolidations on communities across the state? In addition, how will communities address the impact of out-migration of young adults? Young adults provide the natural increase for a population base when they have children. Declining numbers of young adults will have an impact on future population growth. Moreover, young adults add vitality, new thoughts, and new ideas to their communities. They are also the newest generation of workers. The loss of this "human capital" will have significant effects on the state. Finally, are counties and the state positioned to offer services to a growing elderly population? Do they have adequate and appropriate housing? How should they deal with those elderly who are isolated? These and other concerns will be important topics of debate among policy-makers.

# Introduction (continued)

**Table A. Population Trends in North Dakota by County: 1980 - 2020**

County	Census Population Counts			Population Projections			
	1980	1990	2000	2005	2010	2015	2020

## Methodology

---

Baseline census figures for North Dakota are presented in this report by age and gender for 1980, 1990, and 2000 along with projections for the years 2005, 2010, 2015 and 2020. This report updates the projections released in January 1999 (Rathge, et.al., 1999). The new projections were developed using a standard cohort-survival model. These new figures were based on census trends that reflect downward movement among most rural counties and upward growth among the counties with larger urban centers. Our assumptions reflect a weakening of the flow of North Dakota's population from the farmsteads and small rural communities into the metropolitan centers which will have a moderating effect on the state's population. In addition, the state's largest populated counties will continue to grow thus resulting in a modest growth pattern for North Dakota over the next two decades.

### Cohort-Survival Model

A cohort-survival model is one of the most commonly used projection techniques. In brief, a set of rates for births, deaths, and migration are applied to baseline population figures to determine the population at a later point in time. Generally, this technique assumes that these rates will continue unchanged, in a linear fashion, through the course of the projection period. Although complete stability in rates is unlikely, the model does provide a reasoned scenario for projecting the size and distribution of future populations. However, adjustments were made to the linear modeling, especially in the case of small counties, when such trends resulted in an unreasonable outcome. For example, it is unlikely that any age cohort would decline to zero, though this scenario would have been projected in several counties if the model was left uncorrected. The assumptions made about trends in births, deaths, and migration are described below.

#### *Birth Rates*

The number of births projected to occur in each county was derived from age-specific fertility rates. These rates were based on a three-year average of the total number of births to mothers by age cohort for the years 1998 through 2000. The three-year average was used to control for year-to-year variations. Fertility rates were calculated for mothers between 15 and 44 years of age. Births occurring to mothers outside these ages were averaged into the top and bottom age cohorts. County-specific fertility rates were used in the model. It was assumed that these rates would continue throughout the projection period.

#### *Death Rates*

Rates of death in North Dakota are very similar among counties. Therefore, a single statewide rate was used for all counties. The rates reflect age- and gender-specific mortality based on an average for the years 1998 through 2000. Once again, the three-year average controlled for year-to-year fluctuations in deaths. The actual rates were calculated using a standard life table (Hamm and Azam, 1991).

#### *Migration Rates*

Age- and gender-specific migration rates were calculated using a residual technique (Shryock and Siegel, 1976). The rates reflect the age-specific migration patterns from 1990 to 2000. In some cases, the migration rates for counties with small populations were modified to better reflect historical trends. For example, in some counties the number of residents in various age groups is extremely small. Slight changes in these age groups can result in sizeable migration rates which do not accurately reflect the migration experience. Therefore, migration rates were moderated in extreme cases.

### Limitations of Population Projections

Population projections are mathematical calculations that illustrate what the population will be in the future if specific assumptions persist throughout the projection period. Although information depicting North Dakota's resident population is relatively accurate, the ability to forecast substantial changes in any socio-economic or demographic process which may alter current population trends is tenuous at best. Therefore, it is wise to utilize these projections with caution. They should not be viewed as the sole element in planning or decision-making, rather as only one tool in the process.

# Organization of State and County Data Profiles

## North Dakota County Map

A map of North Dakota highlighting the location of each county is included in each data profile. The map below shows the names and locations of each of the state's 53 counties.

## Quick Facts

Quick facts are included to provide some background information for the state and each of its 53 counties. Data, except for the capital and county seat, come from the 2000 Decennial Census and can be found online at the U.S. Census Bureau's website: <http://www.census.gov>. Quick facts included are:

- North Dakota's capital and the county seat for each county
- North Dakota's national population rank and the state population rank of each of the counties (population for the United States in 2000 was 281,421,906)
- The median age in years for North Dakota and each county (median age for the United States in 2000 was 35.3)
- The number of persons per square mile, or population density, for North Dakota and each county (persons per square mile for the United States in 2000 was 79.6)

## Population Trends

The *Population Trends: 1920 - 2020* charts show the population trendline for the state and each county using U.S. Census Bureau data from 1920 through 2000. The population projections through 2020 are also shown, as a dotted extension of the census trendline. At 642,200 in 2000, North Dakota has shown a 5.7 percent decrease in population since its peak in 1930 at 680,845. The state's population is projected to increase by 1.4 percent by 2020, to 651,291. The trends for most counties show continued population decline, except for those counties that have larger urban centers, which show increases in population.

## **Organization of State and County Data Profiles (continued)**

---

### **Census Population Counts (Table 1)**

Table 1 consists of the census population counts by age and gender, as well as totals, for the state and each county in 1980, 1990, and 2000. The population is divided into seventeen 5-year age cohorts, starting with 0 to 4, in addition to the final cumulative cohort of persons age 85 and older. Table 1 offers a useful historical context to the population projections in Table 2.

### **Population Pyramids**

Population pyramids are used in this report to illustrate the age-specific distribution of the population. Two pyramids are generated for the state and each county. The first represents the population distribution as enumerated during the 2000 Census. The second pyramid illustrates what the population distribution is projected to look like in the year 2020, though significant changes in socio-economic and demographic trends could alter this distribution. Each bar in the pyramid represents a 5-year age cohort with males depicted on the left and females on the right. The bottom bar on the graph represents the youngest age cohort, persons 0 to 4 years of age. The top bar represents those seniors age 85 and older. The bars are in percentages, thus the pyramid provides an easy way to see the relative distribution of the population by age and gender.

The best way to interpret population pyramids is to compare and contrast the bars that represent age cohorts. The smaller the bar, the smaller that age cohort is relative to others. For example, when viewing North Dakota's pyramid for 2000 on page 2, one can quickly see that the three bars representing the young adult population (i.e., ages 20-24, 25-29, and 30-34) are among the smallest of all age cohorts in the state. This reflects the significant loss of young adults in North Dakota through out-migration. In turn, the loss of young adults has a direct effect on the number of births. Persons in the age cohorts from 20 to 34 are primarily responsible for new births in the state. It is not surprising, therefore, that the bar representing persons under the age of 5 is also relatively small. In contrast, the size of the bars representing the baby-boom population, those born between 1946 and 1962, is the largest in the state (i.e., age cohorts 40-44, 45-49, 50-54, 55-59). The senior population also is relatively large and the proportion of elderly is growing (i.e., persons 65 years of age and older) in North Dakota. Contrasting the pyramid for 2000 with 2020 on page 2, one can quickly see the changes that are expected in each age cohort given current trends. On a statewide level, for example, the bars representing the age cohorts become very uniform. This means the proportion of elderly will increase, becoming very similar to younger cohorts in size. For most counties, however, the elderly will represent the largest proportion of all age groups.

### **Population Projections (Table 2)**

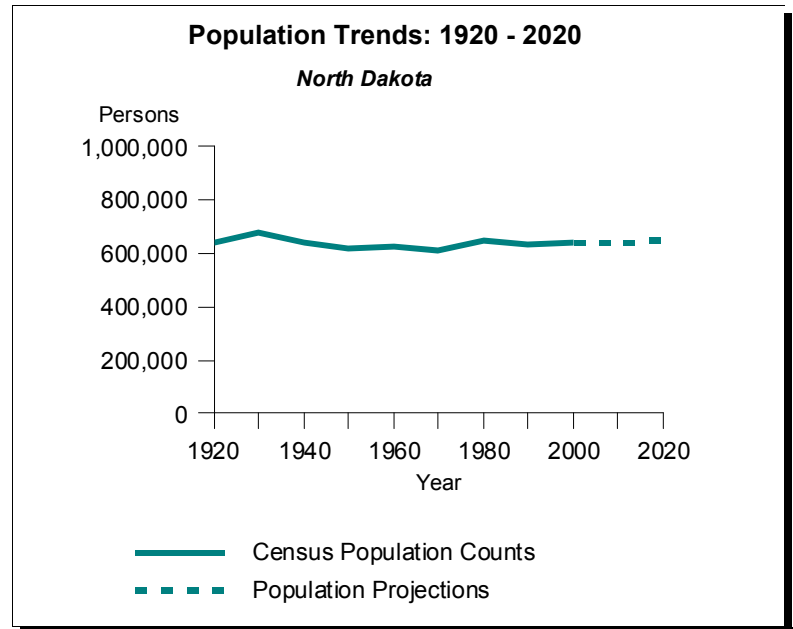

Table 2 consists of the population projections by age and gender, as well as totals, for the state and each county for 2005, 2010, 2015, and 2020. The population is divided into seventeen 5-year age cohorts, starting with 0 to 4, in addition to the final cumulative cohort of persons age 85 and older. The projections were determined using the Cohort-Survival Model described in the Methodology section.
